

Public Introduction

Quantum Time-Energy Theory (QTET) is a first-principle framework proposing that time is organized through coherence, resonance, and entropy rather than treated only as an independent background parameter. In QTET, resonance acts as an anchor for coherence against entropy, allowing ordered structure to persist and evolve within closed or semi-closed systems.

Within this framework, the QTL-Sphere serves as a cosmological model in which large-scale structure is treated as nested and resonance-governed. Time is organized through the Echo Meridian, the temporal–coherence axis through which alignment, deviation, and recurrence can be interpreted.

QTET requires a departure from standard cosmological models because its governing tensor structure requires a closed framework. In this theory, temporal ordering, structural recurrence, and deviation are governed by tensor-defined coherence relations, so cosmology cannot be based primarily on open expansion dynamics alone. Instead, large-scale structure and chronology must be interpreted through a closed, resonance-governed system in which time and order emerge from coherence, resonance, and entropy together.

Using the current QTET/QTL-Sphere simulation framework, the present cosmological age estimate is approximately 13.8 billion years. In this sense, the framework reproduces the familiar present-age estimate while preserving a distinct internal structural logic. The simulation set further indicates stable coherence ordering, bounded deviation rather than uncontrolled drift, and structured continuation beyond the regime where standard descriptions are often treated as flattening.

Highlights from the current simulation release

The QTL-Sphere chronology remained internally coherent across the tested simulation set. Deviation patterns were structured and bounded, not random.

The current chronology framework produced a present-age estimate of approximately 13.8 billion years.

In comparison against an external cosmological reference, the QTET/QTL-Sphere trace remained close across the anchored range while preserving a different internal interpretation of temporal and structural ordering.

The broader simulation set suggests that cosmological continuation may remain dynamically ordered beyond the regime where standard models are often treated as asymptotically flattening.

The Echo Meridian is presented publicly as the temporal–coherence axis of the framework.

This release is intended as a public introduction to the QTET/QTL-Sphere framework and its current simulation outputs. It is offered as an invitation to discussion around an alternative first-principle approach to cosmology, coherence, temporal structure, and large-scale ordering.
